Digital Alarm Clock

Digital Design Lab Final Project

Sarah Brown

I. INTRODUCTION

This course focused on various features and applications of the LPC1769, this project works to tie this experience together into one cohesive design. The project serves as a prototype for a digital alarm clock. Based on the features selected from the requirements, this prototype is able to accept user input with a series of switches. This user input is used for various features and centers on keeping track of time and related functions. One display uses input to set the time to the correct local time. An alarm clock can be set to be triggered at a specific time, once it is triggered it will display a different screen alerting the user to the alarm and play the song Oklahoma (like the OU clock tower). In addition, another display serves as a stopwatch and shows the elapsed time. This allows the user to start, stop, and reset the timer.

Points	Function	Description / Minimum Requirements	Status
1	Time of Day	Keep track the current time and be able to display it as decimal hours, minutes, and seconds.	Working
1	Alarm Clock	When the current time matches a user specified time, generate an alarm	Working
1	Elapsed Time	Display elapsed time. The user should be able to start, stop, and reset the timer. Must display at least minutes and seconds and go up to at least 99 minutes and 59 seconds.	Working
0.5	Character LCD	Use an LCD module with an HD44780 (or compatible) Controller	Working
0.5	Serially Controlled Display	Use SPI or I2C interface to read at least 4 switches	Working
0.5	Serially Interfaced Switches	Use SPI or I2C interface to read at least 4 switches	Working
0.5	Melody Alarm	Play a simple melody for the alarm condition (at least 8 notes and 4 frequencies)	Working
5			

Table 1: Summary of selected and implemented features

II. DIRECTIONS FOR USE

The alarm clock prototype has three main parts of interest for users: the LCD display and its contrast control, the speaker and its volume control, and four different buttons. To begin use of the clock, power must be supplied. Power is supplied via the USB connection on the LPC1769 for the 3.3 V components and via an USB power supply for the 5V components. To ensure no faults occur, users should make sure that the 3.3 V and 5 V power rails do not come in contact in the prototype.

After the clock prototype is powered, the clock is initialized at 0 hours, 0 minutes, and 0 seconds and begins to measure time. With the use of the serially interfaced switches, different displays can be reached. The main display, shown on start-up, shows the

current time and what other displays the blue, white, and green buttons can navigate to. On the main display, the red button simply returns the user to the main display to ensure continuity across the displays and thus has no function.

From the main display, the blue button can be used to navigate to a settings menu to set the clock's time. On this display, the clock time is paused so time will not pass. However, the user can use the blue button to set the seconds, the white button to set the minutes, and the green button to set the hours. The user input is display on the LCD display to help the user select the proper time. Once the desired time is set, the red button is then pressed to return to the main display and to resume the clock.

From the main display, the white button can be used to navigate to a settings menu to set the time of the alarm. Here the user can set the alarm to a given hour and minute combination. For the alarm, the second value is preset to 0 seconds to allow for the blue button to be used for other input. The blue button is used to toggle the alarm on and off, the white button is used to set the minute value of the alarm, and the green button is used to set the hour value. The set alarm time and the alarm status are both displayed on the LCD screen. The red button can be used to return to the main display.

From the main display, the green button can be used to navigate to the stopwatch function. Here the user can start, stop, and reset a counter displaying the elapsed time. The blue button is used to toggle the stopwatch status from counting to stopped and vice versa, the white button is used to reset the amount of time that has elapsed, and the green button is unused. The elapsed time is shown on the LCD screen. The red button can be used to return to the main display.

	Red Button	Blue Button	White Button	Green Button
Main Display	Return to Main Display	Set Time	Set Alarm	Stopwatch
Set Time	Return to Main Display	Set Seconds	Set Minutes	Set Hours
Set Alarm	Return to Main Display	Toggle Alarm On/Off	Set Minutes	Set Hours
Stopwatch	Return to Main Display	Toggle Stopwatch	Reset Time Elapsed	Unused

III. Design Analysis

The clock prototype incorporates various design elements from the different labs this semester. However, due to the different requirements for this project, many of the variables had to be recalculated. These values were related to the core building blocks of the software solution and include values to change the CPU clock frequency, values to control I2C communication, values to setup the RIT and generate various frequency notes, and values to control the RTC and its interrupts. In addition, values had to be determined for the various components for the hardware solution. These values were pull-up resistors, the resistor for the LCD backlight, and the amplifier circuit.

Part	Quantity
LPCXpresso1769/CD	1
MCP23017 I/O Expander	1
TC2004A-01 20x4 LCD Display	1
4-channel I2C-safe Bi-directional Logic Level Converter - BSS138	1
LM386 Amplifier	1
Speaker	1
TP2104N3	1
Push Button	4
10k Pull-up Resistors	3
330 Pull-up Resistor	1
100k Potentiometer	1
10k Potentiometer	1
100 uF Capacitor	1
0.1 uF Capacitor	1
5v Power Supply	1

Table 3: Bill of Materials

A. Hardware Design

The hardware solution for the alarm clock prototype provides support for the LCD display to show output to the user while also interfacing with user input to change different clock variables. The LCD display operates off of 5V while the LPC1769 operates off of 3.3V. Therefore, to use I2C communication between the LPC1769 and the LCD display, a logic shifter is included to shift the SDA and SCL lines from 3.3 V to 5 V. This is done with an Adafruit level shifter that uses BSS138 FETs with 10K pull-up resistors. This chips shifts to logic levels which are then used to communicate with the MPC23017 expander chip which then interfaces with the input buttons and the LCD display.

The LCD display includes a backlight, this backlight has an operating voltage of 4.2 V with a forward current of 180 mA. A resistor can then be selected from these specifications to ensure that the backlight LED is within its safety limits.

$$180\ mA = \frac{5V - 4.2\ V}{R}$$

$$\text{R} = 4.4\ \Omega$$

As any resistor greater than 5 Ω will be within the safety limits, a 330 Ω resistor is selected due to preference in backlight brightness. This results in a current of 2.4 mA which is within the safety limits.

$$I_{330\Omega} = \frac{5V - 4.2\ V}{330\Omega} = 2.4\ mA$$

The MCP23017 has internal weak pull-up resistors (100 kΩ) which can be enabled to internally pull up inputs. This allows for the four input buttons to be pulled up via the MCP23017 instead of with additional resistors.

Two pull-up resistors are used on the SDA and SCL lines to pull the lines up to 3.3 V. In addition, one pull-up resistor is used with a TP2104 FET to control the power to the amplifier circuit. This FET is used to limit noise produced by the speaker due to feedback from the I2C communication. All three of these pull-up resistors were selected to be a standard value of 10k. The standard value of 10k meets the specifications for I2C communication for the pull-up resistors for SDA and SCL. This is computed to be within two bounds:

$$\frac{V_{DD}}{I_{OL}} < R \ll \frac{t_{cycle}}{3C} = \frac{1}{3fC}$$

Here the I2C clock frequency must be set to an appropriate value (less than or equal to 100 kHz). C is the effective capacitance between the 3 devices tied in parallel to SCL, assuming each device is 10pF, this results in a C of 30pF for the 3 devices. V_{DD} is 3.3V and the smallest I_{OL} for the various devices is 3mA (the TC74 and the MCP23017 both at 3mA and the LPC1769 at 4mA). This results in the following bounds:

$$\frac{3.3V}{3mA} < R \ll \frac{1}{3(100kHz)(30pF)}$$
$$1.1\ kOhm < R \ll 111\ kOhm$$

Selecting a R value in the middles of 10 kΩ, gives the following values.

$$t_r \approx 3RC$$
$$t_r \approx 3(10000)(30 * 10^{-12})$$
$$t_r \approx 900\ nanoseconds$$
$$t_r \ll \frac{1}{f}$$
$$900\ ns \ll \frac{1}{100{,}000}$$
$$900\ ns \ll 10\ \mu s$$

And:

$$I = \frac{3.3V}{10\ kOhm} = 0.33mA$$

Finally, the last of the hardware calculations were to calibrate the gain of an amplifier circuit. This amplifier circuit is used with the speaker to produce the alarm sound. This is done with an LM386. However, the LM386's default gain of 21 would result in clipping so a voltage divider was utilized to avoid clipping. By using a 100 kΩ potentiometer, the gain can be adjusted to adjust the volume output. This allows to adjust to minimize and remove clipping. In addition, this allows for quieter volume levels for testing.

B. Software Design

The software solution for the alarm clock prototype controls the LCD display to show output to the user while also receiving input from the user to change various options within the clock.

The CPU clock frequency is set to 100 MHz to allow for precision with frequencies generated with the RIT. By using the main oscillator as the PLL0 clock source in the LPC1769, it is possible to start with a square signal of 12 MHz. This can be selected by setting the CLKSRCSEL value to 01 (page 36 in documentation). There is also an internal PLL feature that can be used to divide and multiply the signal. The 12 MHz signal is used as a base and the final signal is output on pin 1.27 on PAD10 so this must be appropriately configured as an output.

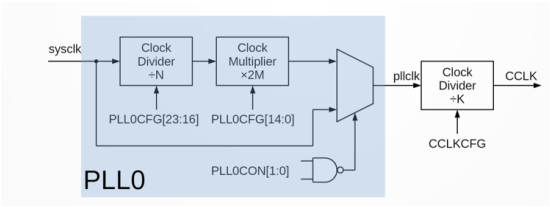

Figure 2: Details about the internal PLL in the LPC1769.

Examples in the LPC1769 documentation can be followed to calculate appropriate values to plug into the code and the registers.

The PLL inputs and settings must meet the following:

- F_{IN} is in the range of 32 kHz to 50 MHz
- F_{CCO} is in the range of 275 MHz to 550 MHz

FCCO can be found as follows, but as we want it to be a multiple of 100 so by selecting it as 300 MHz the equivalent N can be found. Since N, M, and K are required to be an integer values, N can be found by inspection. As 300/2=150/12=12.5 and 12.5*2 = 25 which is an integer. This lets us select M to be 25 and N to be 2.

$$F_{CCO} = \frac{(2)(M)(F_{in})}{N}$$

$$N = \frac{(2)(M)(12\ MHz)}{300\ MHz}$$

$$2 = \frac{(2)(25)(12\ MHz)}{300\ MHz}$$

K can be found as follows:

$$K = \frac{(F_{CCO})}{(F_{out})}$$

$$K = \frac{(300 * 10^6)}{(100 * 10^6)}$$

$$K = 3$$

However, since the code is 0 indexed each parameter should have an one subtracted from it leaving the values at: M = 25-1=24, K = 3-1=2, and N = 2-1=1. These values produce a clock value of 100 MHz.

The I2C data rate is controlled by I2CxSCLH and I2CxSCLL. This frequency is standard at 100 kHz so as it is based on the PCLK value and thus the CCLK value, it must be divided as the current clock CPU frequency is 100 MHz.

$$Freq = \frac{PCLK}{I2CxSCLH + I2CxSCLL}$$

PCLK is set to CCLK value/4 by default. This leaves it at PCLK = 100 MHz/4 = 25 MHz. Then I2CxSCLH and I2CxSCLL are set equal to each other to ensure a duty cycle of 50%. Setting these values both to 125 gives:

$$Freq = \frac{25\ MHz}{125 + 125} = 100\ kHz$$

The RIT is then configured to allow use of interrupts at a given match frequency. The interrupt creates a square wave at that given match frequency and decreases the wave amplitude over a short period of time. This period of time is dependent on whether or not the note is a whole note, a half note, a quarter note, or an eighth note. In addition, the same function that selects the note frequency and note duration, selects between whether the note is a rest note of a given size instead of producing a note. This allows for various notes to be played and can be used to create a melody alarm.

The variable for the RICOMP for these notes is calculated with the following:

$$Match\ Frequency\ Value = \frac{CCLK}{Note\ Freq * 2}$$

Using this equation, variables were found for the middle c octave as well as some notes from the fifth octave. Using simple sheet music, song functions were created to play various alarm melodies. The sheet music can be seen in Appendix 3: Sheet Music. Song functions were created to play the introduction of Oklahoma, to intimate the OU clock tower, and to play the introduction of the Pokémon theme song. Which melody is played during the alarm is currently hardcoded into the alarm clock prototype, but in a continued design could have additional songs as well as options to select between different songs.

The Real Time Clock is used to set and then measure the passage of time. This is done with various RTC control and data registers. The RTC also has interrupts for a set alarm and a counter interrupt that can be set to trigger on the increase of a unit of time (e.g. seconds). The use of these interrupts makes it possible to set and trigger an alarm and to measure and display the elapsed time.

Finally, in various initialization functions and while writing to the LCD display, waits are needed. The wait_ticks function from lab 1 was recalibrated to account for the 100 MHz clock. This resulted in a linear function as shown below.

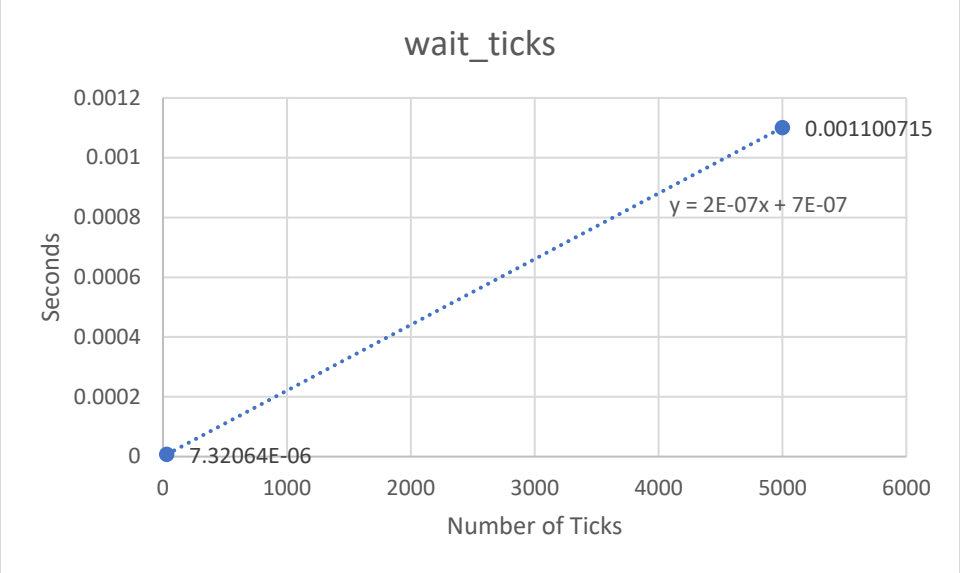

Figure 3: A graph created in Excel showing the equation for the wait_ticks() function.

$$y = 2 * 10^{-7} + 7 * 10^{-7}$$

IV. Conclusion

With the use of knowledge from throughout the semester it is possible to create a prototype for a digital clock with various features. This clock can be used as an alarm clock as well as a stopwatch to measure the elapsed time. Future developments of this prototype could include using a different display to allow for pixel level control as well as using a different microcontroller to allow for a smaller device than possible with the LPC1769. The complete schematic and the complete software are shown in the appendix.
